

The Opioid-Abuse Predictor

Morgan Durham, Srimann Ramachandrani, Thomas Lever, and Dr. Heman Shakeri
Howard University, Virginia Commonwealth University and University of Virginia

Introduction

The opioid epidemic has had severe consequences on public health, leading to hundreds of American deaths daily and burdening the health care system. Identifying those at risk of opioid aberrant drug-related behavior (ADRB) is crucial. However, traditional tools like the Opioid Risk Tool (ORT) are limited by self-reported measures. Alternatively, machine-learning algorithms, particularly recurrent neural networks (RNNs), offer a new approach to analyzing this data. RNNs can effectively consider temporal variations in medications, conditions, and other factors. Implementing an RNN-based machine learning model would significantly improve the identification of individuals at risk of opioid abuse.

Methods

Through SQL queries, we obtained patient time-series data on conditions and medications from Research All of Us. Selecting specific conceptual features from Deaver et al. and other reputable sources, we constructed a feature matrix of patient-visit information. Subsequently, we trained an LSTM RNN model using our chosen features.

Objectives

The Opioid-Abuse Predictor aims to enhance clinical decision-making by identifying individuals at risk of opioid abuse, improving patient safety during opioid prescriptions. The Opioid-Abuse Predictor mobilizes Research All of Us EHR data and employs advanced technologies such as LSTM RNNs and factor analysis to explore temporal dependencies among medication, procedures, lab results, and diagnosis histories. The predictor serves as a modern, user-friendly foundation for future research endeavors, aiming to provide more precise predictions of opioid abuse.

Top 10 Conditions Features

Top 10 Medication Features

Expected Results

Despite encountering setbacks, we remain optimistic about the predictor's ability yield favorable results. Our confidence stems from the strong support provided by previous literature and the extensive research conducted by Research All of Us, which reinforces the belief that the selected features are indeed suitable predictors for opioid abuse.
